

AI Coworker Description

AI Coworkers:

(for UEM only proposal: [UEM Only AI Coworkers](#))

Example of Building an AI Coworker [AI Coworker Interface - v0 by Vercel](#)

1. Problem Statement

MSPs spend an enormous amount of time performing repeatable operational tasks. While we will do our best to supply AI Agents and Experts to support their tasks, prebuilt experts will not cover all needs

- MSPs/customers will need to customize agents
- Customization will be tied to [their runbooks/SOPs](#) and *their use cases and* their scripts
- Many of these tasks are already scriptable, but scripts are risky to run, and often gated by expertise or permissions.

AI coworkers are the way we take AI Expert Agents and allow MSPs to modify their tasks, learn new skills, and call Scripts (or other deterministic action-taking devices).

Value Statement When MSPs can customize their AI agents in our secure environment, “The outcome for the MSP is you reduce the number of technicians that you need to deliver the services that you have.”

2. Product Vision

AI Coworkers are trusted, task-oriented AI agents that work alongside MSP technicians.

They do three things well:

- Understand intent
- Choose the safest viable action
- Deliver measurable time savings

They are not autonomous free-for-alls. They operate inside guardrails defined by N-able and the MSP.

They:

- Take labor and turn it into software/automation
- Supply Business Resilience at machine speed
- Are supported by [a control pane for the MSPs and for internal efficiency](#)

3. Core Concepts

AI Coworkers

An AI Coworker is a configurable AI agent designed to handle a specific category of work, such as patching, remediation, compliance, or scripting.

Each coworker is composed of:

- One or more **AI Experts**
- [A Runbook defined by N-able or the customer \(AKA SKILLS\)](#)
- Connections to one or more **MCP servers** (N-able ships default coworkers for common MSP use cases. Customers can clone and customize them.)

- One or more Tools (aka run Script or call action) which may happen outside of the context of the AI Agent (to reduce token utilization and increase determinism)

AI Experts

AI Experts are specialized AI agents with a clearly defined scope.

Each AI Expert:

- Has an explicit runbook that defines how it reasons and acts
- Is attached to one or more MCP servers
- Can recommend or execute Actions based on risk and permissions
- AI Experts do not act outside their runbook.
- AI Experts are owned and managed by n-able

MCP Servers and Tools

MCP servers expose data or access to secondary locations. They include tools.

There may also be Tools associated with an AI agent that are not in the MCP Server that AI Agents can call.

Tools may:

- Retrieve data
- Make decisions
- Take action
- One important tool type is the **Script Repository access**
 - The Script Repository is a curated, MSP-approved collection of scripts.

Key properties:

Scripts are explicitly approved by the MSP

Each script has a risk classification: low, medium, or high

Running a script is considered an **action**

Scripts represent trusted automation

- **Execution Flow where a Script is involved**

A. Script Exists and Is Approved

User makes a request to an AI Coworker (or it is a time trigger or otherwise triggered)

The coworker routes the request to one or more AI Experts to evaluate the request against its runbook. If the request requires it,

The Expert searches the Script Repository

If a matching script exists:

The Expert recommends the script

The script is executed automatically if:

The action is low risk (aka a risk that is at or below the users' risk tolerance), or

The user has granted permission

All action, reasoning, etc is logged and explained

B. Script Does Not Exist

If no existing script or tool can solve the request:

The AI Expert calls a **Script Generator Expert**

The Script Generator designs a new script

The script is presented to the user for review

The user can:

Approve and run it (if permitted)

Publish it to the Script Repository (if permitted)

Submit it for approval if they lack permissions

Once approved, the script becomes reusable for future requests.

Permissions and Risk Model

All actions respect:

User permissions/token permissions

MSP approval policies

Script risk levels

If a user cannot approve or run a script:

The AI clearly explains why

The AI suggests the appropriate next step, such as submitting the script for approval

No hidden automation is allowed

Customer Created Coworkers

Customers can:

Clone default N-able coworkers

Modify the runbook(Adjust behavior and scope)

Add or remove MCPs/tools

Custom coworkers can be:

Run on demand

Triggered by events

Executed on a schedule

This enables MSPs to encode their own SOPs workflows and other vendors into AI coworkers.

We should build the UX to this up front. This does not need to be second

8. **Value Tracking**

Each AI Coworker has an associated **Value Score**.

Value is defined as:

Estimated time to complete the task manually

Versus time to complete the task with the AI Coworker

There may be secondary values like 'additional devices managed' , license fees saved, etc. we should design for this up front.

The coworkers ship w default values and are adjustable w permissions

A **Value Ledger** tracks:

Time saved per action/value added on each run

Aggregate value added per coworker

Cumulative value over time

This makes AI value visible, measurable, and defensible.

Promoting Agent behavior from 'Human in the loop' to 'Autonomous'

There is a trustworthiness issue when people first generate and utilize AI Agents and Coworkers.

In an experiment done by @Ewan Cameron

He Hypothesizes : “ We believe that... the concept of L4 earned autonomy — where an AI Expert co-worker graduates from "human confirms" to "AI executes, human audits" — can be represented as a coherent, self-evident UX concept that a mature MSP would immediately understand without explanation. Specifically, that one of three competing mental models (track record, graduated dial, or scope-based guardrail) will survive a 10-second comprehension test and provoke an instinctive opinion about whether they'd engage with it.”

In this experiment, we see the AI Experts and AI Coworkers listed as a Task Category, and their outcomes/actions are assigned a trust-execution level.

AI RECOMMENDATION

Recommended: Assisted Mode for Patch Management

Based on your recent 30-day uptime metrics (99.98%), we recommend maintaining "Assisted" mode for OS-level patches to ensure zero-day compatibility checks remain human-verified.

TASK CATEGORY	MANUAL	ASSISTED	AUTONOMOUS
Patch Management OS updates, security patches, and application rollouts.	☐	☒	☐
User Onboarding Account creation, license assignment, and hardware provisioning.	☐	☐	☒
Security Remediation Threat containment, firewall updates, and suspicious process isolation.	☒	☐	☐
Hardware Monitoring Resource threshold alerts, temp monitoring, and failure prediction.	☐	☐	☒
Network Topology Optimization VLAN tagging, traffic shaping, and dynamic path rerouting.	☐	☒	☐

Define Behavior with Runbooks

Runbooks define how your AI Coworker responds to situations. Choose a template to start.

Basic Response
Simple acknowledgment and status update

Diagnostic Flow
Gather system info before action

Smart Escalation
Auto-escalate based on complexity

Custom Logic
Define your own decision tree

Configure Guardrails

Set boundaries for what your AI Coworker can do autonomously vs. what requires approval.

Execution Rules

Auto-execute low-risk scripts
No approval needed

Require approval for medium-risk
Quick one-click approval

Manual execution for high-risk
Technician must run manually

Additional Settings

Audit logging
Log all actions for compliance

Notify on execution
Send alerts when scripts run
